$\qquad$

Any molecule containing only $\qquad$ atoms has a $\qquad$ shape.

To predict shapes of molecules with more than 2 atoms we use the VSEPR theory:

- VSEPR stands for $\qquad$ - $\qquad$ , $\qquad$ - $\qquad$
- Since electrons $\qquad$ each other, electrons pairs will be as
$\qquad$ apart as possible.

| shape | number of atoms bonded to central atom | number of unshared pairs of electrons | example |
| :---: | :---: | :---: | :---: |
| linear $\text { (__ }{ }^{\circ} \text { angle) }$ |  |  | $O=C=O$ |
| trigonal planar 0 angles $)$ |  |  | $\begin{gathered} H_{1} \\ H^{\prime}=0 \end{gathered}$ |
| tetrahedral $\qquad$ angles) |  |  |  |
| bent |  |  |  |
| trigonal pyramidal |  |  |  |

## Polar Molecules:

- must contain at least one $\qquad$ bond
- are shaped so that there is a $\qquad$ and a $\qquad$ end
example of a polar molecule:

Non-polar Molecule:

- contains only $\qquad$ bonds -or-
- contains polar bonds, but has no
example of a non-polar molecule:

## Intermolecular Forces

- $\qquad$ of attraction $\qquad$ molecules
- are $\qquad$ than covalent and ionic bonds
- 3 types:

1. Dipole-dipole forces:

- force of attraction between the $\qquad$ end of one $\qquad$ and the $\qquad$ end of another molecule
- the $\qquad$ of all the intermolecular forces

2. Hydrogen Bonding:

- occurs in molecules with H - $\qquad$ H $\qquad$ , and H - $\qquad$ bonds
- large $\qquad$ charge on H is attracted to an
$\qquad$ pair of electrons on a neighboring $\qquad$

3. London Dispersion Forces:
intermolecular forces resulting from constant of $\qquad$

- the only type of intermolecular force between nonpolar molecules
